# Search space and brute force

If all you have is a hammer, everything looks like a nail

## Search Space

Ensemble of all solutions we have to choose from to get the optimal answer

Often what is asked from us is not the solution but one of its properties

## Search Space on an example : minimum pair

• Find the minimum pair on the list IE the pair with the minimum sum

0 5 8 6 -1 4 9 10 2

Search space : all the pairs

### Make sense of your search space

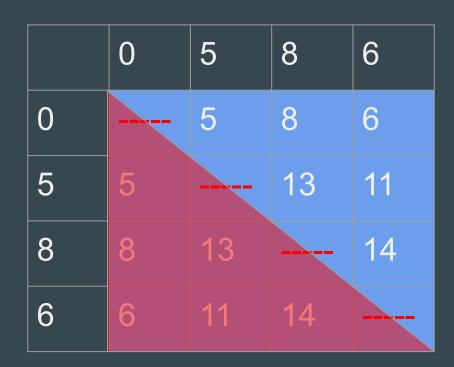

Another representation:

Matrix where

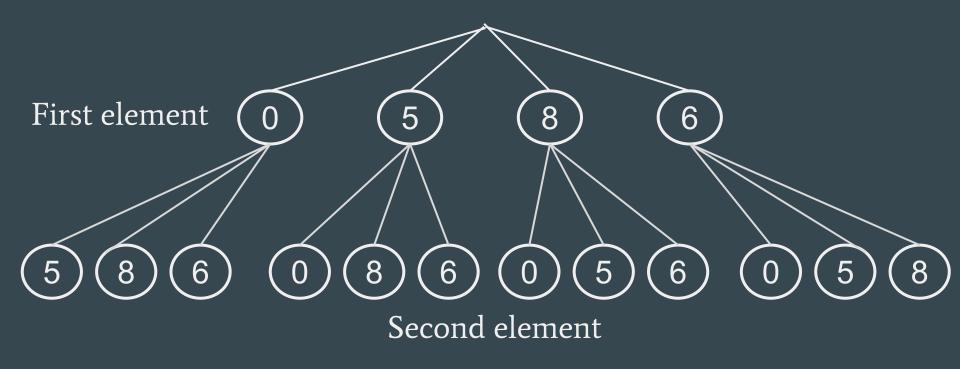

line: first element of the pair

Column: second element

Implementation: two for loops

# Make sense of your search space

### Brute force - introduction

Example: I want to find all subsets of a set which sum is 42

### I can:

- make a list of all subsets
- for each subset, calculate the sum and check if it is 42

Search space: all subsets of the array

*Test:* the sum is 42

A brute force search has a search space and a test

### Brute force - construct the search space

The python module itertools provides useful tools to construct the search space. See <a href="https://docs.python.org/3/library/itertools.html">https://docs.python.org/3/library/itertools.html</a>

```
>>> list(product("ab", "cd"))
[('a', 'c'), ('a', 'd'), ('b', 'c'), ('b', 'd')]
>>> list(permutations("abc", 2))
[('a', 'b'), ('a', 'c'), ('b', 'a'), ('b', 'c'), ('c', 'a'), ('c', 'b')]
>>> list(combinations("abc", 2))
[('a', 'b'), ('a', 'c'), ('b', 'c')]
>>> list(combinations_with_replacement("abc", 2))
[('a', 'a'), ('a', 'b'), ('a', 'c'), ('b', 'b'), ('b', 'c'), ('c', 'c')]
```

*Note:* we use list() because the return values are *lazy-evaluated* iterables

→ these are very useful to save memory

product(q<sub>1</sub>,q<sub>2</sub>,...,[repeat=1])

product('ABCD', repeat=2)

AA AB AC AD BA BB BC BD CA CB CC CD DA DB DC DD

Can take multiple iterables and output the cartesian product between them

The repeat field indicate how many time do we take the iterables

Complexity :  $O((\prod q_i)^{repeat})$ 

Where q<sub>i</sub> is the size of each iterable

permutation(p, [r=len(p)])

permutations('ABCD', 2)

AB AC AD BA BC BD CA CB CD DA DB DC

Take an iterable and create every permutation of length r

A permutation is an ordered (order is important) of element without repetition

Complexity :  $O(\frac{p!}{(p-r)!})$  For example with r=2, the complexity is p\*(p-1)

Where p is used as the size of the iterable p

combinations(p, r)

combinations('ABCD', 2)

AB AC AD BC BD CD

Take an iterable and create every combination of length r

A combination is a non ordered of element without repetition, since it is non ordered, AB and BA are the same

Complexity: 
$$O(\binom{p}{r}) = O(\frac{p!}{r!(p-r)!})$$

Where p is used as the size of the iterable p

combinations\_with\_replacement(p, r)

Take an iterable and create every combination of length r with replacement

Same as combination, but we can repeat the same element multiple times

Complexity: 
$$O(\binom{p+r-1}{r}) = O(\frac{(p+r-1)!}{r!(p-1)!})$$

Where p is used as the size of the iterable p

### Brute force - let's solve our example

```
IN:
10 12 25 30 17 8 14 9 6

OUT:
(12, 30)
(25, 17)
(25, 8, 9)
(10, 12, 14, 6)
(10, 17, 9, 6)
```

**gen** is Python magic called a *generator expression*. Ask me if you want to know more.

### Why not to use brute force

There is a problem called *combinatorial explosion*Cf <a href="https://en.wikipedia.org/wiki/Combinatorial\_explosion">https://en.wikipedia.org/wiki/Combinatorial\_explosion</a>

Tl; dr: the search space is often a lot bigger than the input size (e.g exponential)

Previous example: for an array of size n, there are 2<sup>n</sup> - 1 non-empty subsets...

### Why <del>not</del> to use brute force

- Brute force is a good way to **test** if more complicated algorithms are correct (you compare their results on small sets)
- Sometimes you just don't know a better algorithm

But, can't we reduce the search space a little bit?

 $\rightarrow$  often you can use *backtracking* (see you next week)
